# Questions

- 1) What is the 3D structure of circulation in SDWSC?
- 2) How does the circulation change over semi-diurnal, diel, and spring-neap cycles?
- 3) How do circulation and stratification affect DO?
- 4) Can we model the system to determine fundamental mechanisms, and predict conditions under different natural forcings and management scenarios?

# Semi-implicit 3D (Si3D) Model

Developed by USGS (Pete Smith) as part of the Interagency Ecological Program for San Francisco Bay/Delta

Support provided by:

- U.S. Geological Survey
- CA Dept. of Water Resources
- U.S. Bureau of Reclamation

# Field Data Collection

- Up to three 1-month studies
- 2-days of concentrated transects of velocity and water quality during each month
- 2 tracer studies

# First Field Study August 2 – September 2, 2004

# 30-hour single site study August 9 & August 16, 2004

- SCAMP microstructure profiler:
  - vertical turbulent mixing rates

- SeaBird SBE-25 profiles:
  - temperature, conductivity, Chl-a, obs, transmissivity, DO, PAR

- Pump and filter water for laboratory analysis at 5 depths every 2-hours:
  - $\text{NH}_4$ ,  $\text{NO}_3$ , TKN

# Moorings

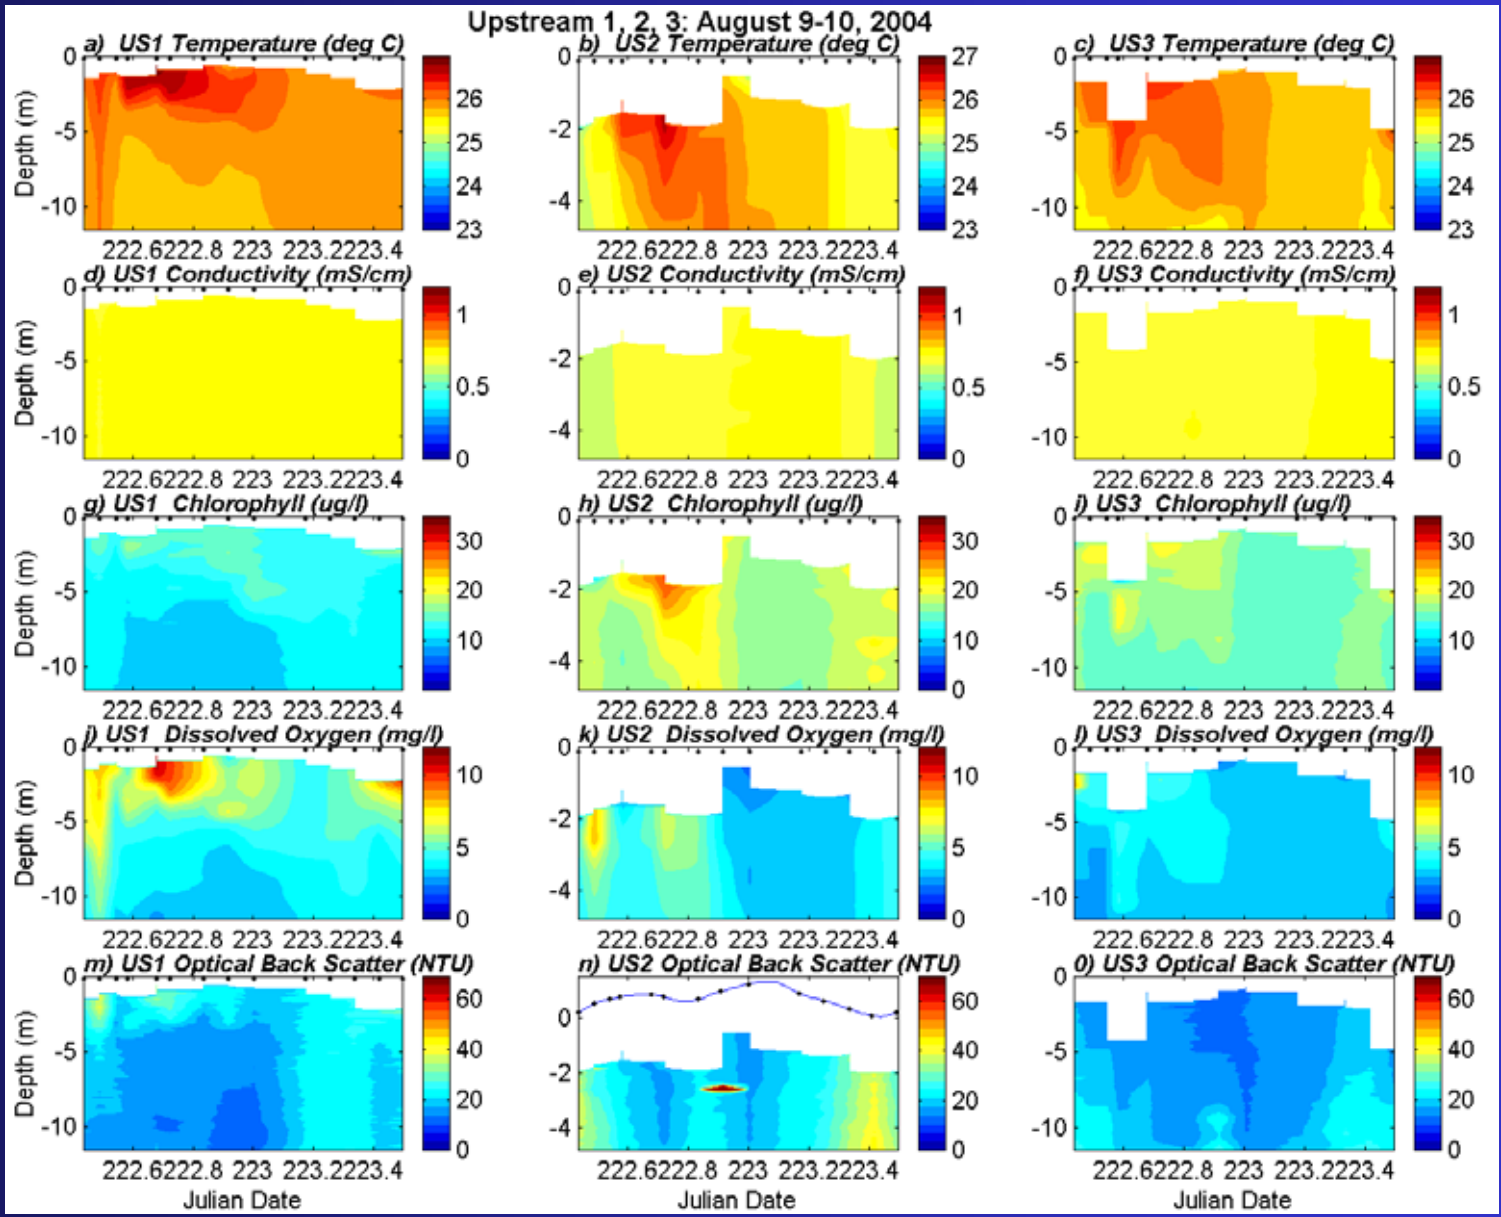

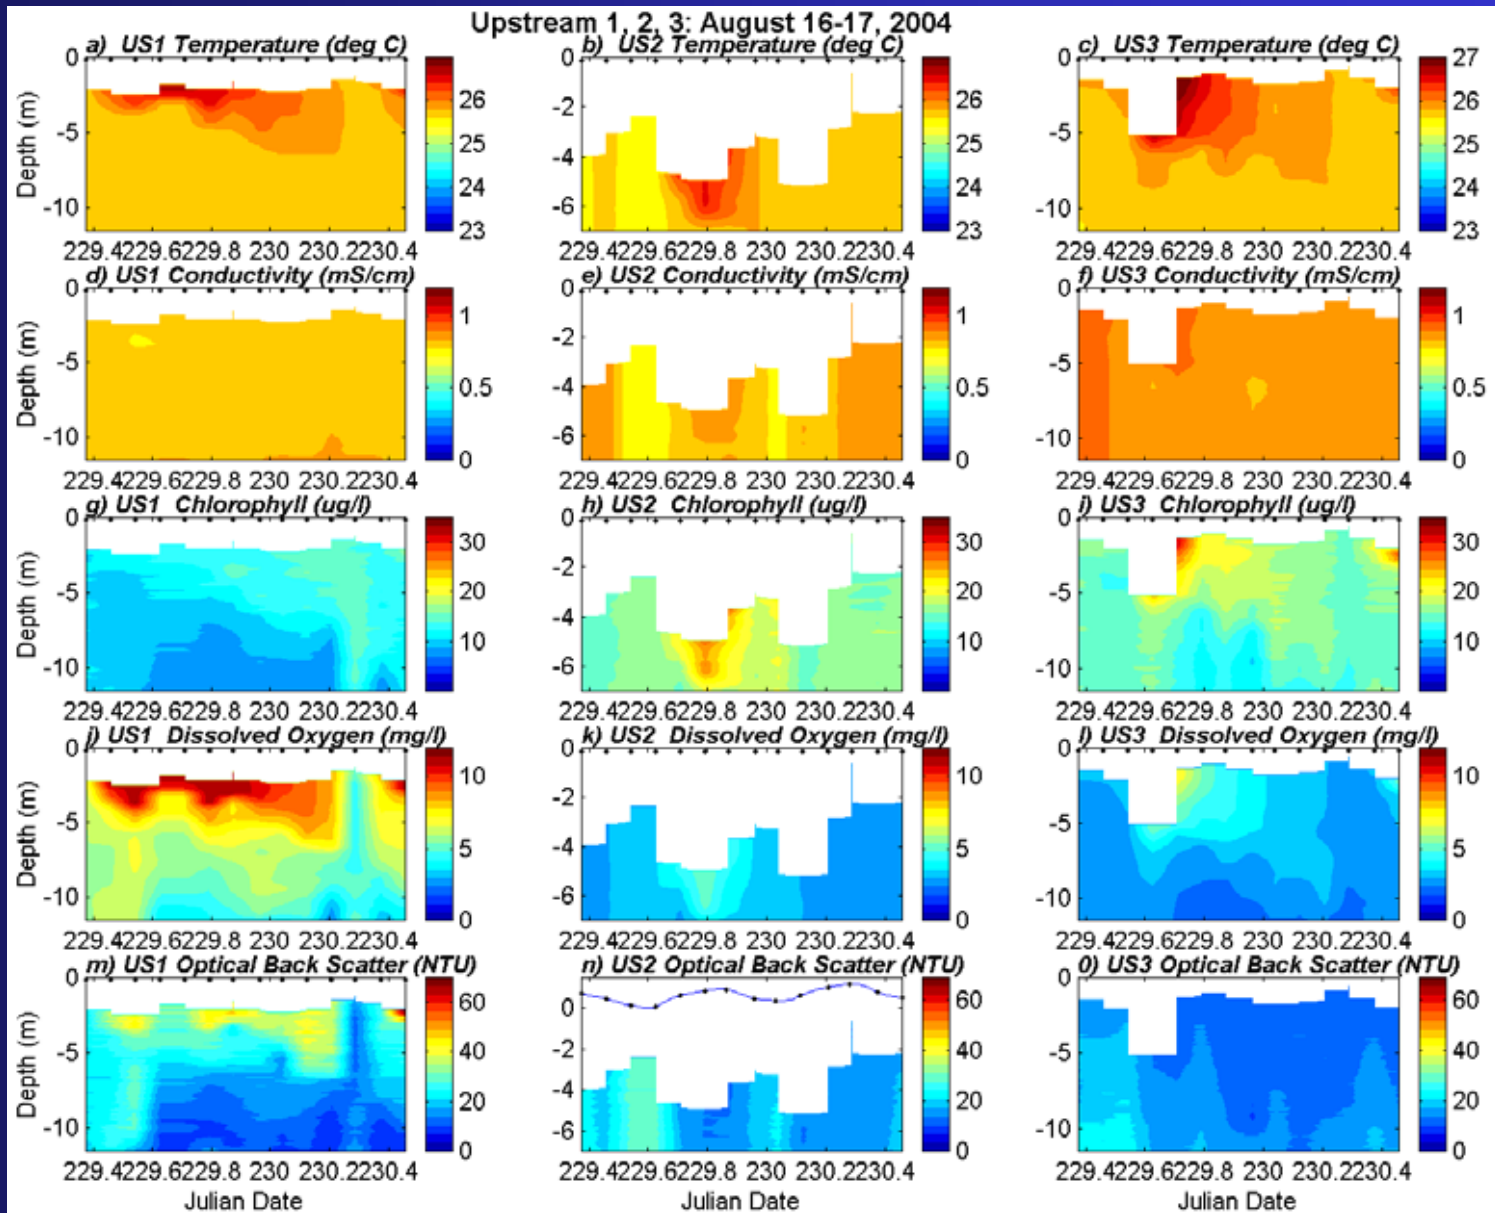

# Moorings

## Next step

Finish velocity data from fixed ADCPs

Finish temperature string data

Incorporate water quality data analysis

Concentrate on the junction

Move upstream boundary condition

Need improved resolution on grid

Plan next field investigation effort

# The End
